

Test - 02-05-2026

1. var → It is a keyword to declare variable,  
It is traditional way of declaring  
→ Initialization, redeclaration, reassignment are possible

let → It is a keyword to declare variable  
→ Initialization, reassignment are possible

const → only Initialization is possible

2. Truthy Values & Falsy values

→ Truthy values are the values which are equivalent to boolean value of true

Eg: number, string, " " → space, true

→ Falsy values are the values which are equivalent to boolean value false

Eg: undefined, empty string, false, NaN

## Hoisting :

→ Hoisting occurs when we try to access a variable before its declaration & initialization.

→ ~~The JS~~ when it occurs JS searches for the variable and move the declaration part to the top of the scope

→ If it is a variable from var it returns undefined

→ If it is let ~~and~~ const It gives error, ~~and~~

4. == & ===

→ Both are comparison operators

== compares the value only

=== compares both the value and datatype

5. Callback function :

→ when a function is passed as an argument to another function is called callback function

6. For Each ()

→ For each iterates the function for the each element present in the array

Map()

→ Map transforms each element and returns new array

7. Arrow function

→ It is a shorter way to write function

# React

## 1. React

- React is not a programming language.
- It is a library made using JavaScript
- It is a component based architecture
- It is mainly used for creating single page web application without reloading

## 2. JSX

- JSX stands for JavaScript XML
- It is a JavaScript code that returns HTML

JSX cannot be understood by browsers directly, For that transpiling is required

### 3. Props:

- > Properties are the read only data passed from Parent to child component.
- > used for communication between components

### State

- > State is like a variable that holds the data
- > It is used for dynamic behaviour

### 4. Use State()

- > `useState()` is a React Hook that adds state to a functional component

### 5. `useEffect()`

- > It is a React Hook used to handle side effects in functional components.
- > used for timers and subscriptions

### 6. Virtual Dom:

- > It is like a DOM instead of re-rendering fully it compares with previous values and renders the required component only.

## 7. state update :

→ when state updates it re renders the component. The component which changes from previous memory state. i.e. the Virtual Dom compares the previous state and update the changed component only

## 8. Key

→ Key is used to help React efficiently identify, update, and manage list elements during re rendering
